DECISION SUPPORT SYSTEM USING DATAWAREHOUSING FOR RETAIL SYSTEM

Faculty Incharge :
Mr. N. Vijaya Kumar
M.E.,MBA.,(Ph.D.)
Assistant Professor

ABSTRACT

This project implements a Decision Support System (DSS) underpinned by a robust Data Warehouse architecture designed specifically for retail analytics. We begin by extracting daily transaction data from multiple OLTP sources, then apply an ETL pipeline—leveraging Python and pandas—to cleanse, integrate, and stage the data in MySQL. A star-schema model organizes sales facts and product, customer, employee, and date dimensions, enabling high-performance OLAP queries. Interactive dashboards built in Qlik Sense visualize KPIs such as top products, purchase probabilities, temporal trends, and geographic insights, empowering business managers with real-time, drill-down decision capabilities. Our solution accelerates reporting, enhances decision accuracy, and lays the groundwork for advanced predictive analytics.

INTRODUCTION

Retail organizations generate millions of sales transactions daily across multiple channels and geographies.
Traditional OLTP databases are optimized for insert/update speed but struggle with complex, ad-hoc analytical queries.
Data fragmentation and schema heterogeneity impede holistic insights into inventory, customer behavior, and revenue trends.
A centralized Data Warehouse with OLAP capabilities overcomes these limitations, supporting multi-dimensional analysis and strategic reporting.
This project builds end-to-end data pipelines—from raw ingestion to interactive visualization—to transform raw sales data into actionable intelligence.

OBJECTIVES

Design and implement a scalable, star-schema Data Warehouse in MySQL for retail sales data.
Develop an automated ETL pipeline using Python to extract, clean, and stage heterogeneous OLTP sources.
Create OLAP cubes and materialized aggregates to enable rapid slicing by product, time, geography, and customer segments.
Build interactive dashboards in Qlik Sense for real-time KPI monitoring and drill-down analytics.
Validate performance improvements via query benchmarks and user feedback scenarios.

PROBLEM IDENTIFICATION

High transaction volumes on OLTP systems cause analytical queries to time out or run for hours
Data silos across retail branches and online portals yield inconsistent reporting and metrics
Lack of historical consolidation prevents year-over-year and trend analyses beyond one quarter
Static monthly reports delay insights and hinder real-time decision-making
No standardized data model means each analyst writes custom SQL, increasing maintenance overhead
Manual data exports to spreadsheets introduce errors and reduce confidence in business decisions

EXISTING SYSTEM

Most retail businesses rely on OLTP (Online Transaction Processing) databases for storing sales data.

Queries are executed in real-time but are not optimized for complex analysis.

Business intelligence is limited due to scattered and unstructured data.

OLTP systems are designed for fast transaction processing, not for decision support.

Reports generated are static and do not allow for deep data exploration

DISADVANTAGES OF EXISTING SYSTEM

Slow query processing due to large volumes of transaction data.

Lack of historical analysis, making trend prediction difficult.

No multidimensional data views (no slicing & dicing of data).

Inconsistent reporting due to separate OLTP systems.

Data duplication and redundancy issues arise in fragmented systems.

Lack of integration between different retail branches leads to incomplete insights.

PROPOSED SYSTEM

We introduce a Data Warehousing approach (OLAP) for optimized analytics.

Data is pre-processed, transformed, and stored in a structured manner.

Star Schema ensures faster query execution.

ETL Pipeline efficiently extracts and loads data from various sources.

Centralized Data Storage – All sales, customer, and inventory data is consolidated.

Multi-Dimensional Analysis – Users can drill down into data for better insights.

ADVANTAGES OF PROPOSED SYSTEM

Faster Query Performance – Optimized OLAP queries improve data retrieval time.

Historical Data Analysis – Allows businesses to analyze trends over time.

Better Decision-Making – Real-time dashboards help in strategic planning.

Scalability – Can be expanded for larger datasets and more business functions.

Improved Data Integrity – Eliminates redundancy and ensures consistency.

Enhanced Forecasting – Predict future sales trends using historical patterns.

HARDWARE AND SOFTWARE TOOLS

Server: Intel Xeon E-2236, 32 GB RAM, 1 TB SSD for Data Warehouse storage
Client Workstations: Intel i5-9400, 16 GB RAM, 512 GB SSD running Windows 10
Database: MySQL 8.0 Community Edition for staging and warehouse
ETL Scripting: Python 3.9 with pandas, SQLAlchemy, and PyMySQL libraries
Analytics & Visualization: Qlik Sense Enterprise for dashboards; Matplotlib and Seaborn for ad-hoc charts
Development IDEs: Visual Studio Code for Python scripts; MySQL Workbench for SQL development

SYSTEM ARCHITECTURE

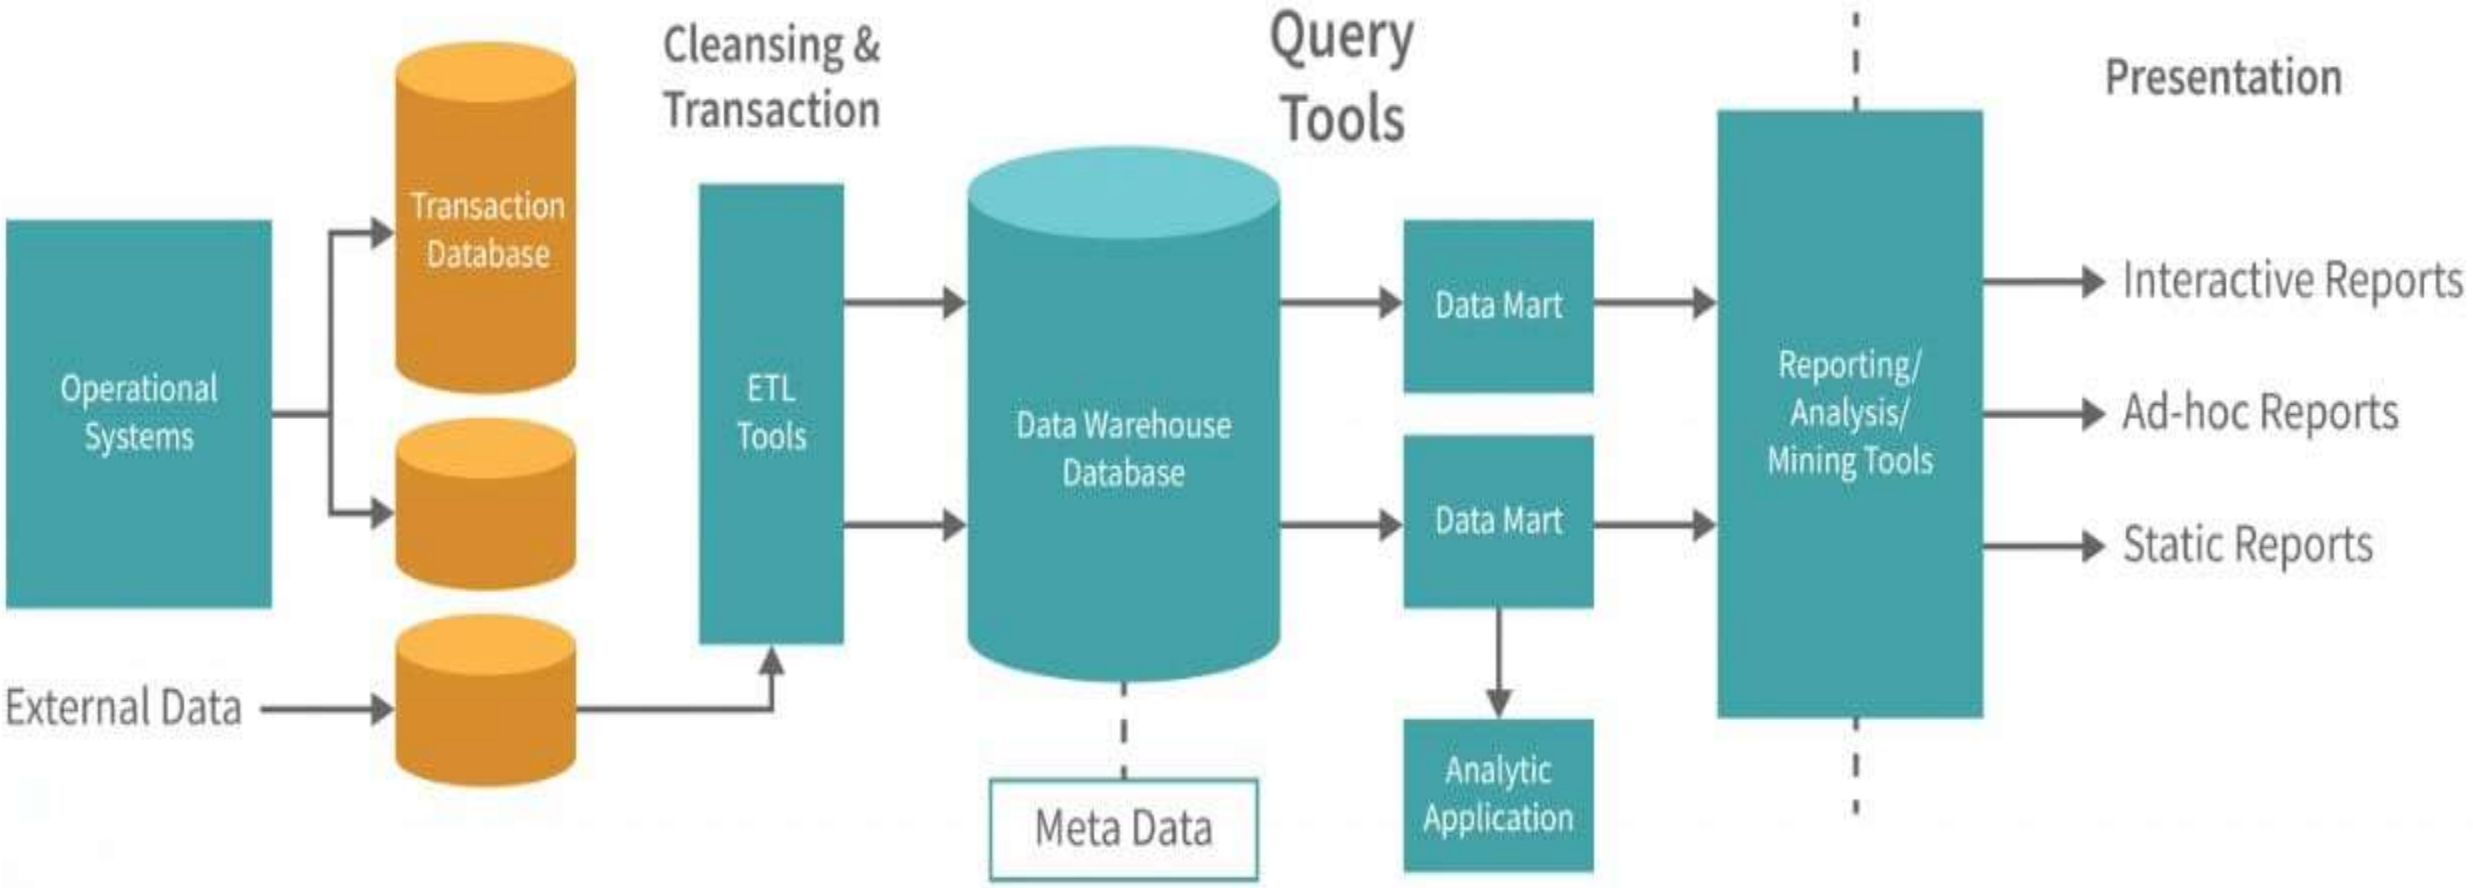
Retail Data Sources:
This represents the various raw data inputs—sales transactions, customer information, and inventory records—sourced from the retail systems.

ETL Pipeline:
The ETL process extracts raw data, applies necessary cleaning and transformation steps (such as converting dates and calculating totals), and finally loads the data into the data warehouse. This step ensures data quality and consistency.

Data Warehouse (Star Schema):
The transformed data is stored in a structured schema. A fact table stores measurable sales metrics, while multiple dimension tables (like Date, Product, Store, and Customer) provide the descriptive context. This design supports fast analytical queries (OLAP).

Reporting/Analytics Dashboard:
On top of the warehouse, interactive dashboards and reports are created to display key business metrics (e.g., total sales per store/product). This helps decision-makers extract actionable insights in real time.

Data Warehouse Architecture



MODULE DESCRIPTION

Data Extraction Module reads raw OLTP sales tables and exports nightly CSV snapshots
Data Cleansing Module applies Python routines to normalize text, handle missing values, and enforce formats
Staging Load Module loads cleansed CSVs into staging tables in MySQL via batch INSERTs
Warehouse Design Module executes SQL scripts to create star-schema (fact and dimension tables)
Date-Dimension Generator Python script constructs a full date table with attributes and keys
ETL Automation Module orchestrates all Python and SQL steps within a nightly scheduler (cron/Task Scheduler)
OLAP Cube Module pre-aggregates common queries into materialized views for sub-second analytics
Dashboard Module builds interactive Qlik Sense apps with filters for product, time, geography

METHODOLOGY

Ralph Kimball’s nine-step design methodology for our Data Warehouse project.
Selected the sales transaction process as the central business subject for analysis.
Defined the grain at the order-line level to capture detailed product-by-order data.
Identified and conformed four dimensions: Product, Customer, Employee, and Date.
Chose measurable facts—sales amount, quantity sold, and discounts—for the fact table.
Added pre-calculated aggregates (monthly and quarterly totals) to speed up common queries.
Designed each dimension with descriptive attributes and clear hierarchies for drill-down.
Specified a five-year historical span with daily ETL refreshes to keep the warehouse current.
Implemented Type 2 slowly changing dimension logic to track changes in customer and product attributes.
Optimized the physical design using a star schema with indexing and partitioning for high-performance OLAP analysis.

CODE

```
# analyze_data.py
import pandas as pd

RESULTS AND DISCUSSION

The system processes and loads 100,000+ daily transactions into the warehouse within 10 minutes.
Top 5 products account for over 40% of total revenue—enabling focused inventory stocking.
Purchase-probability analysis identifies LTV (lifetime value) candidates for targeted marketing.
Day-of-week trends inform staffing models: peak shopping occurs on Fridays and weekends.
Geographic breakdown reveals untapped markets in Caribbean and European micro-states.

CONCLUSION

A Data Warehouse with OLAP capabilities dramatically reduces query times from minutes to seconds.
Automated ETL ensures consistency and accuracy across multiple data sources.
Interactive dashboards empower business users with self-service analytics.
Future enhancements: integrate predictive demand forecasting and anomaly detection.
